Database introduction

by Angel Marchev, Jr.

The idea of a table shouldn't be new to you if you have used Excel, as that has rows and columns of information and the structure of a SQL Server table is similar to that of an Excel spreadsheet

Alice's TOO FREAKING HUGE Client Tracking Spreadsheet ☆

Database

- collection of organized data, information and records
- creating/making a list of classmates, list of relatives, list of friends, telephone directory and so on; you're actually generating a database
- **Structural model** defines how data is organized in a database and also determine the set of operations that can be performed on a data (e.g. relational model)
- **Computer database** are those data/information stored in the computer
- **Database software** allows the user to collect, edit, delete and organize information for easy manage, update and access of the user
- **Microsoft Access** is an example of database software

Types of databases

OPERATIONAL DATABASE

- Dynamic database that is used by any organization in its day to day operation
- Use to collect, maintain, modify and delete data
- e.g. *inventory database*

ANALYTICAL DATABASE

- Static database, wherein data is rarely modified
 - Use to store and track historical data to make long term projections and analysis
 - e.g. *data on global temperature to determine the effects off global warming in a certain areas for a period of time*
- Is the color of blood, and because of this it has historically been associated with sacrifice, danger and courage.

Usecases

ENTITY

- is the term given to the category of information in database
- *A car dealer would be interested in entities such as **clients, cars and salesmen.***
- *A school would be interested in **students, faculty and classes***
- *A bookstore would be interested in **customers, stores, branches and contractors***

Tables

A database **table** is a collection of rows and columns that is used to organize information about a single topic. Each row within a table corresponds to a single record and contains several attributes that describe the row.

These tables are stored in databases

| EmployeeID | LastName | FirstName | Department |
|------------|----------|-----------|------------|
| 100 | Smith | Bob | IT |
| 101 | Jones | Susan | Marketing |
| 102 | Adams | John | Finance |

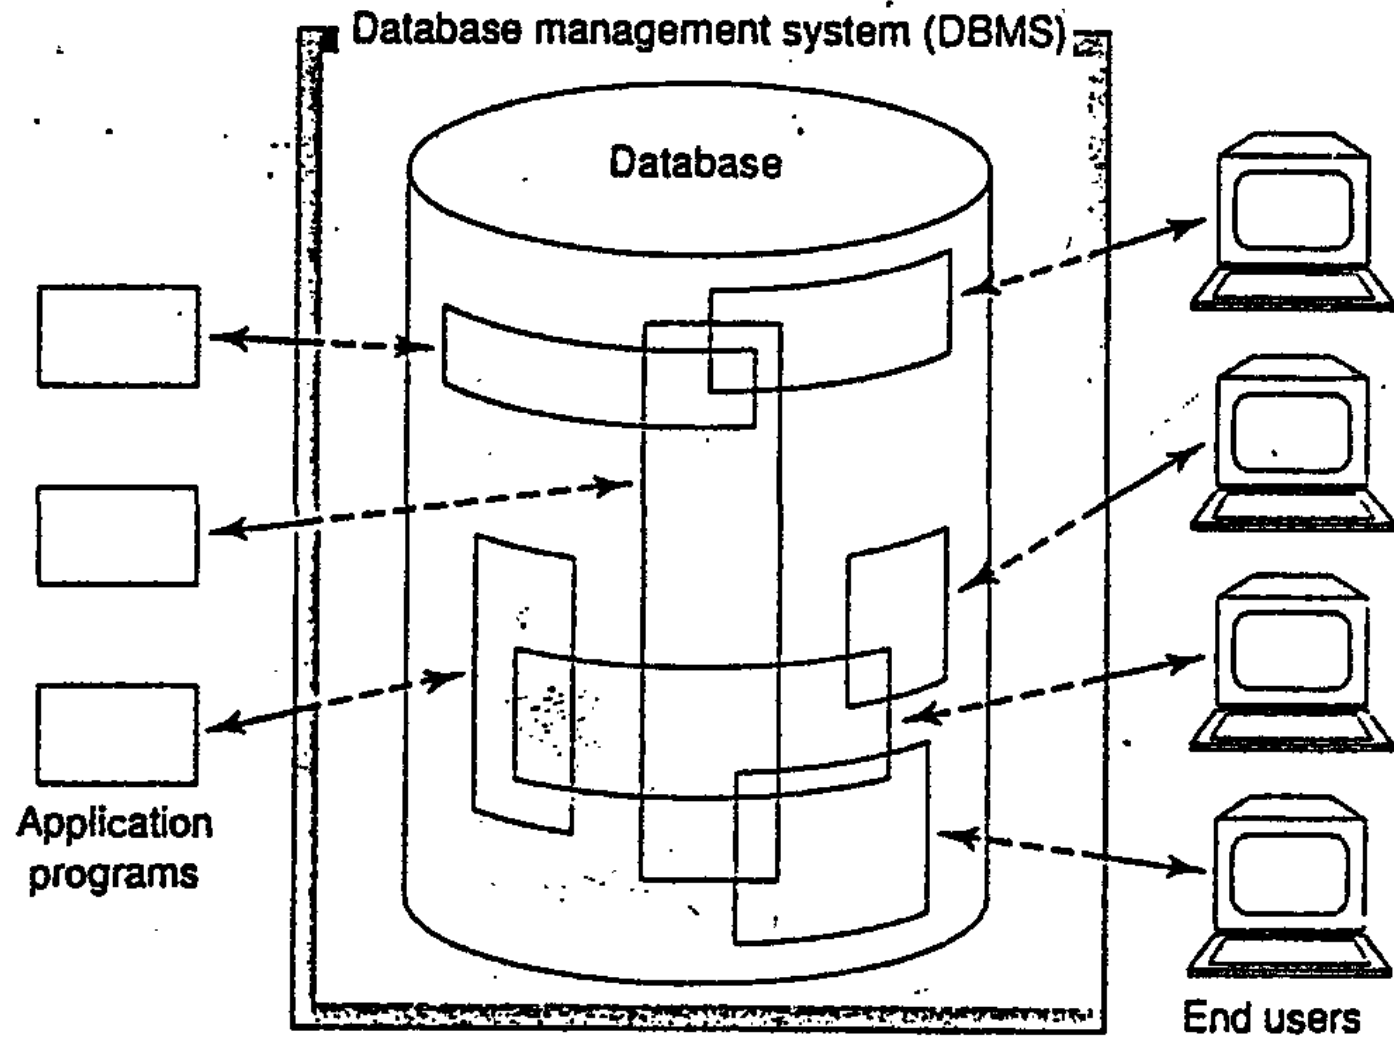

Fig. 1.4 Simplified picture of a database system

Fig. 2.5 Client/server architecture

Fig. 2.7 One server machine, many client machines

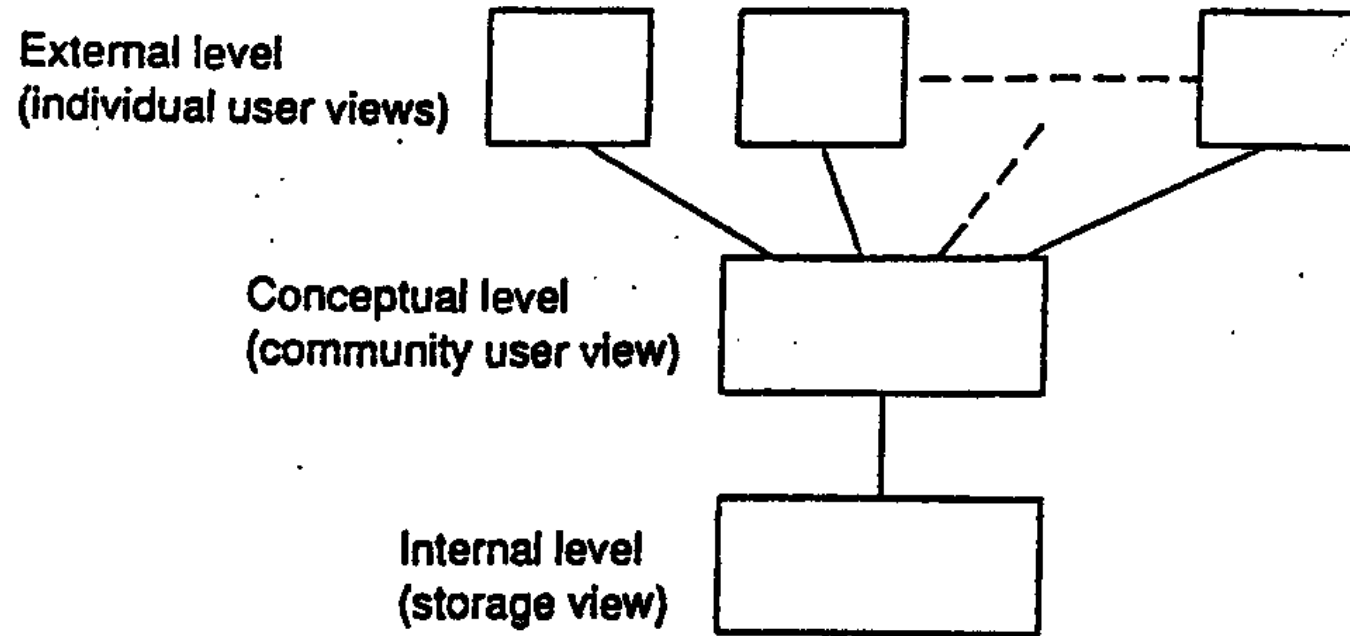

Fig. 2.1 The three levels of the architecture

Data Model

- ▶ A data model is a conceptual representation of the data structures that are required by a database.
- ▶ To use a common analogy, the data model is equivalent to an architect's building plans.
- ▶ A data model is independent of hardware or software constraints.

Type of data models

- ▶ Flat data model
- ▶ Entity relationship model
- ▶ Relation model
- ▶ Record base model
- ▶ Network model
- ▶ Hierarchical model
- ▶ Object oriented data model
- ▶ Object relation model

Flat data model

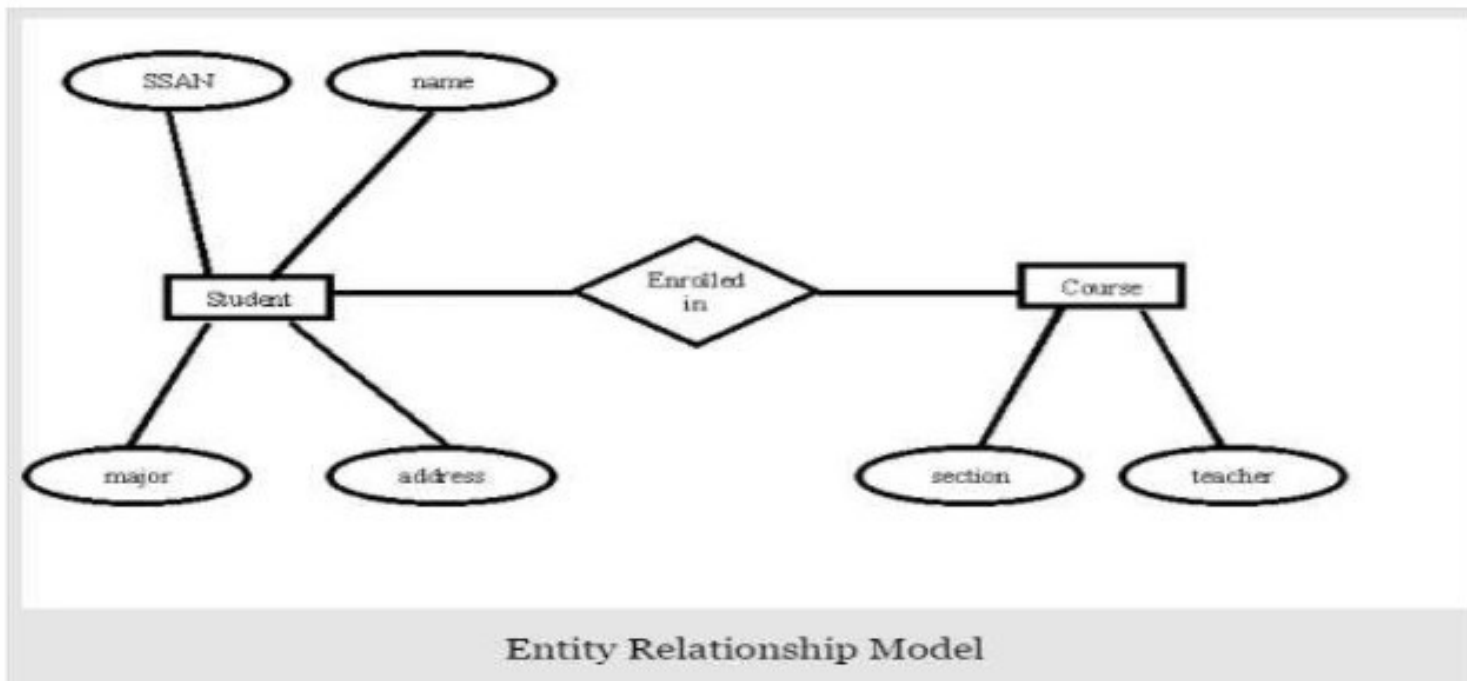

- ▶ Flat data model is the first and foremost introduced model and in this all the data used is kept in the same plane.

| Roll No | Name | Course |
|---------|-------|---------------|
| 5482 | Mark | Web Designing |
| 5486 | Steve | Java |
| 5496 | Smith | Oracle |

Flat Data Model

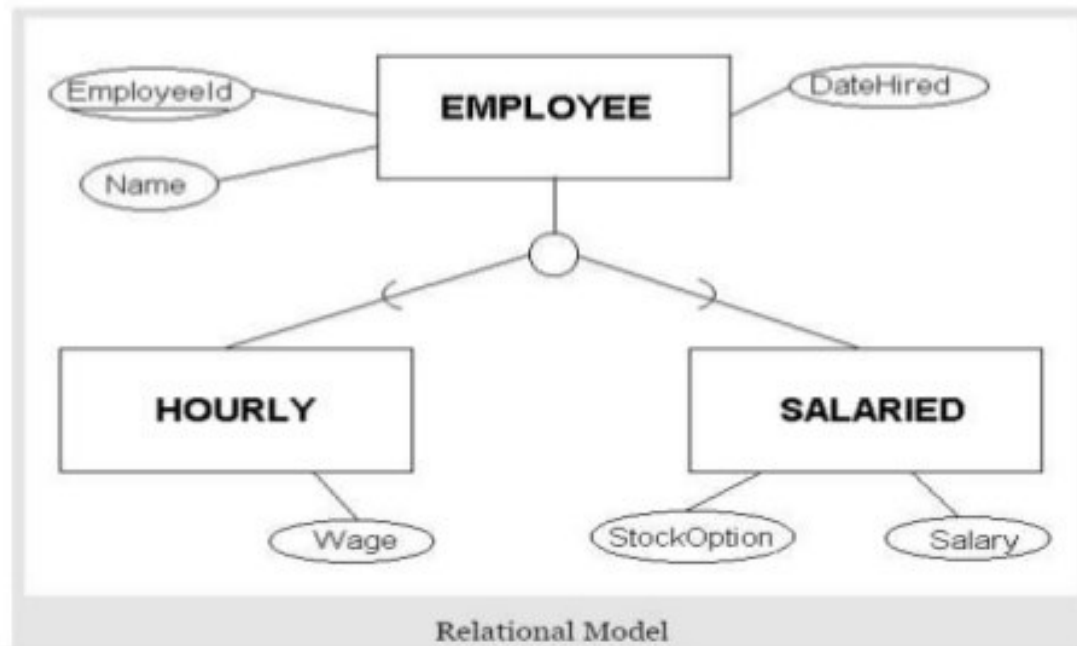

Entity Relationship Data Model

- ▶ Entity relationship model is based on the notion of the real world entities and their relationships.

Relational Data Model

- ▶ Relational model is the most popular model and the most extensively used model. In this model the data can be stored in the tables and this storing is called as relation. Each row in a relation contains unique value and it is called as tuple, each column contains value from same domain and it is called as attribute

Relational databases

A ***relational database*** a collection of tables of data all of which are formally described and organized according to the relational model. Each table must identify a column or group of columns, called the ***PRIMARY KEY***, to uniquely identify each row

Relational DBMS

- Edgar F. Codd at IBM invented the relational database in 1970. Called Father of RDBMS.
- The main elements of RDBMS are based on Codd's 13 rules for a relational system.
- Tables (or relations) are related to each other by sharing common characteristics

Codd's Rules

| | |
|----|-------------------------------------|
| 0 | Foundation Rule |
| 1 | Information Rule |
| 2 | Guaranteed Access |
| 3 | Systematic treatment of null values |
| 4 | Active online Catalogue |
| 5 | Powerful & well structured language |
| 6 | View Updation Rule |
| 7 | Relational level operations |
| 8 | Physical Data independence |
| 9 | Logical Data independence |
| 10 | Integrity Independence |
| 11 | Distribution independence |
| 12 | Non-subversion rule |

RDBMS

A database management system that stores data in the form of **related tables** is called Relational Database Management System.

The goal of RDBMS is to make data easy to store & retrieve

Relational databases help solve problems as they are designed to create tables & then combine the information in interesting ways to create valid information.

things we can do with RDBMS

RDBMS

Typical RDBMS include

Microsoft Access

Microsoft SQL Server

Sybase (The forerunner of Microsoft SQL Server)

IBM DB2

Oracle

Ingres

MySQL

Postgresql etc

RDBMS

Relation Instance:- snapshot of DB

Example: 

| <i>branch-name</i> | <i>branch-city</i> | <i>assets</i> |
|--------------------|--------------------|---------------|
| Brighton | Brooklyn | 7100000 |
| Downtown | Brooklyn | 9000000 |
| Mianus | Horseneck | 400000 |
| North Town | Rye | 3700000 |
| Perryridge | Horseneck | 1700000 |
| Pownal | Bennington | 300000 |
| Redwood | Palo Alto | 2100000 |
| Round Hill | Horseneck | 8000000 |

Schema :- Logical design of DB.

Example:

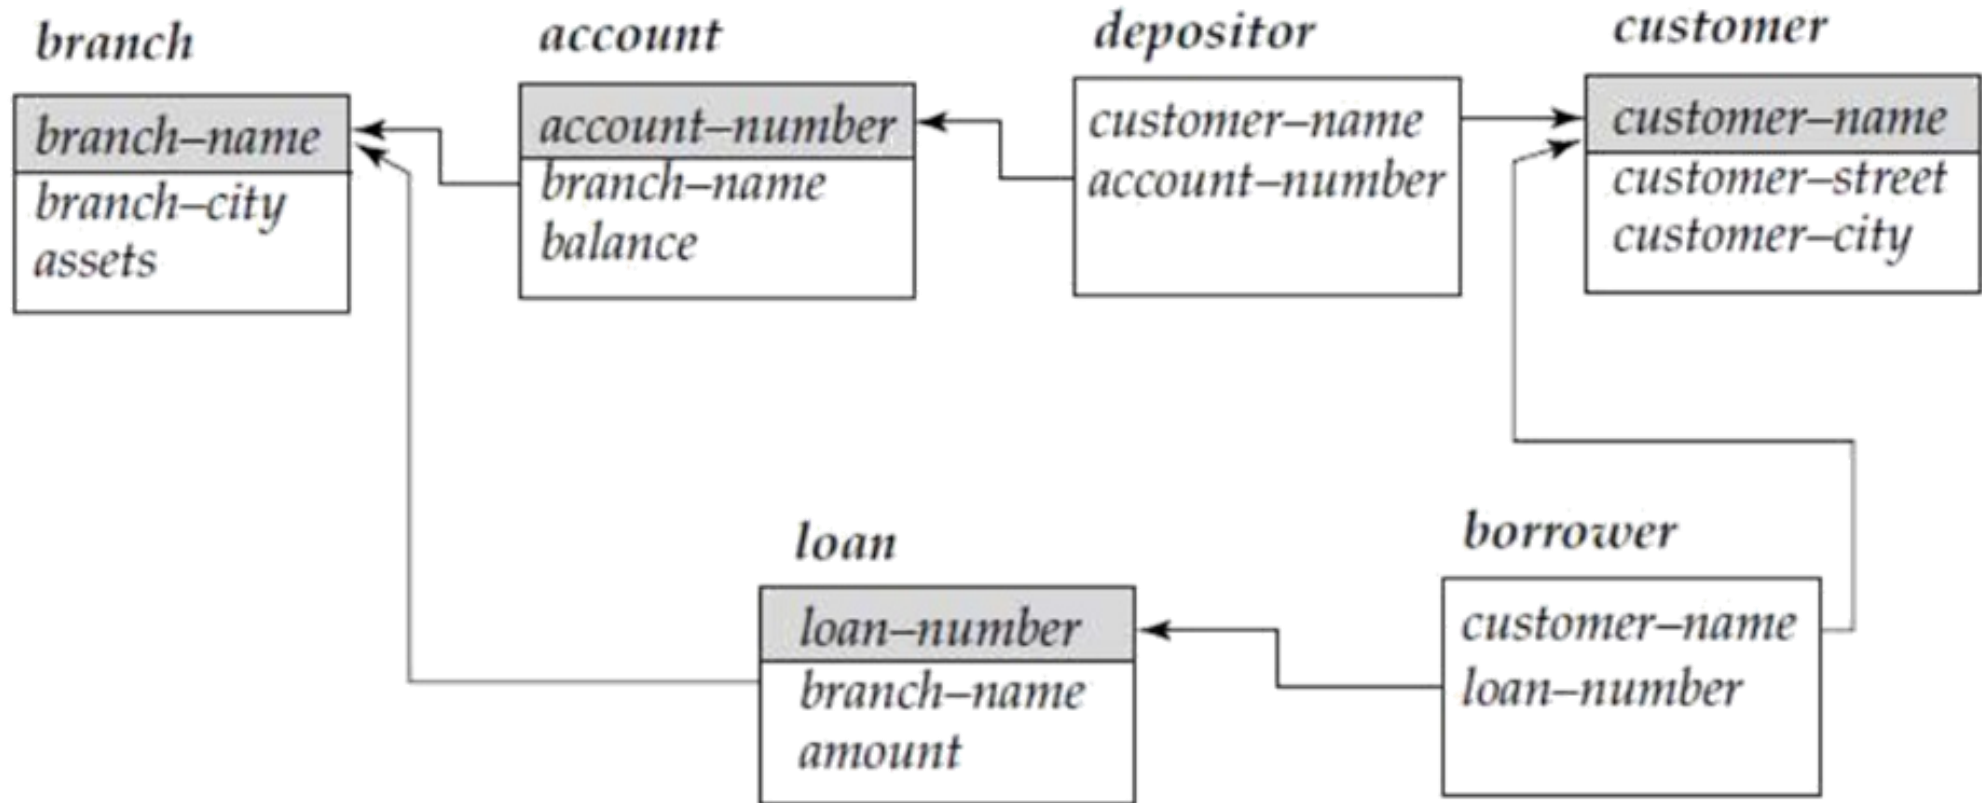

Account-schema = (account-number, branch-name, balance)

Branch-schema = (branch-name, branch-city, assets)

Customer-schema = (customer-name, customer-street, customer-city)

RDBMS

Schema Diagram

Schema diagram for the banking enterprise.

Database operations

by Angel Marchev, Jr.

Normalizing a database

Normalization the process of organizing data in a database that includes creating tables and establishing relationships between the tables

Process is used to help eliminate redundant data

Five ***normalization forms*** (NFs)

1NF: Eliminate Repeating Groups

2NF: Eliminate Redundant Data

3NF: Eliminate Columns Not Dependent on Key

4NF: Isolate Independent Multiple Relationships

5NF: Isolate Semantically Related Multiple Relationships

Example DB normalization

- [db-operations-sample.xlsx](#)

First normal form (1NF)

The ***first normal form*** means the data is in an entity format, which means the following conditions have been met:

- Eliminate repeating groups in individual tables

- Create separate table for each set of related data

- Identify each set of related data with primary key

Do not use multiple fields in a single table to store similar data

Example of normalization

Un-normalized table

| Student# | Advisor | Adv-Room | Class1 | Class2 | Class3 |
|----------|---------|----------|--------|--------|--------|
| 1022 | Jones | 412 | 101-07 | 143-01 | 159-02 |
| 4123 | Smith | 216 | 201-01 | 211-02 | 214-01 |

First Normal Form: No Repeating Groups

| Student# | Advisor | Adv-Room | Class# |
|----------|---------|----------|--------|
| 1022 | Jones | 412 | 101-07 |
| 1022 | Jones | 412 | 143-01 |
| 1022 | Jones | 412 | 159-02 |
| 4123 | Smith | 216 | 201-01 |
| 4123 | Smith | 216 | 211-02 |
| 4123 | Smith | 216 | 214-01 |

Second normal form (2NF)

The ***second normal form*** ensures each attribute describes the entity

- Create separate tables for sets of values that apply to multiple records

- Relate these tables with a foreign key

Records should not depend on anything other than a table's primary key, including a compound key if necessary.

Example of normalization

Second Normal Form: eliminate redundant data

Students:

| Student# | Advisor | Adv-Room |
|----------|---------|----------|
| 1022 | Jones | 412 |
| 4123 | Smith | 216 |

Registration:

| Student# | Class# |
|----------|--------|
| 1022 | 101-07 |
| 1022 | 143-01 |
| 1022 | 159-02 |
| 4123 | 201-01 |
| 4123 | 211-02 |
| 4123 | 214-01 |

Third normal form (3NF)

The ***third normal form*** checks for transitive dependencies.

Eliminate fields that do not depend on the key

Values that are not part of the record's key do not belong in the table

In general if the contents of a group of fields apply to more than a single record, put those fields in a separate table

Example of normalization

Third Normal Form: eliminate data not dependent on the key

Students:

| Student# | Advisor |
|----------|---------|
| 1022 | Jones |
| 4123 | Smith |

Faculty:

| Name | Room | Dept |
|-------|------|------|
| Jones | 412 | 42 |
| Smith | 216 | 42 |

Registration:

| Student# | Class# |
|----------|--------|
| 1022 | 101-07 |
| 1022 | 143-01 |
| 1022 | 159-02 |
| 4123 | 201-01 |
| 4123 | 211-02 |
| 4123 | 214-01 |

Other normalization forms

The fourth normal form is also called the Boyce Codd Normal Form (BCNF) and fifth normal form exists, but are rarely considered in practical design

Disregarding these two additional normalization rules may result in a less than perfect database design but shouldn't affect functionality

Referential integrity

Referential Integrity (RI) is a database concept used to ensure that the relationships between your database tables remains synchronized during data modifications.

RI can be used to ensure the data is clean, may be helpful in optimizing your database environment and can assist in early detection of errors.

A combination of **PRIMARY KEY** and **FOREIGN KEY** constraints can be used to help enforce referential integrity of your database. In addition to a foreign key referencing a primary key constraint, a foreign key can also reference a **UNIQUE** constraint to help maintain referential integrity.

Triggers can also be used to enforce referential integrity, however being triggers require code they don't execute as quickly as table properties such as a primary key constraint.

Methods for enforcing referential integrity

There are several methods available in SQL Server to help maintain database integrity:

- Primary key constraint

- Foreign key constraint

- Unique constraint

- Indexes

- Triggers

Any of these methods can be created as a **composite key** which is an index or constraint created using more than one column. It may be necessary to use more than one column to create a unique value for each row in a table.

PRIMARY KEY constraint

An important concept of designing a database table is the use of a **PRIMARY KEY** — an attribute or set of attributes used to uniquely identify each row

A table can only have one primary key which is created using a primary key constraint and enforced by creating a unique index on the primary key columns

A column that participates in the primary key constraint cannot accept null values

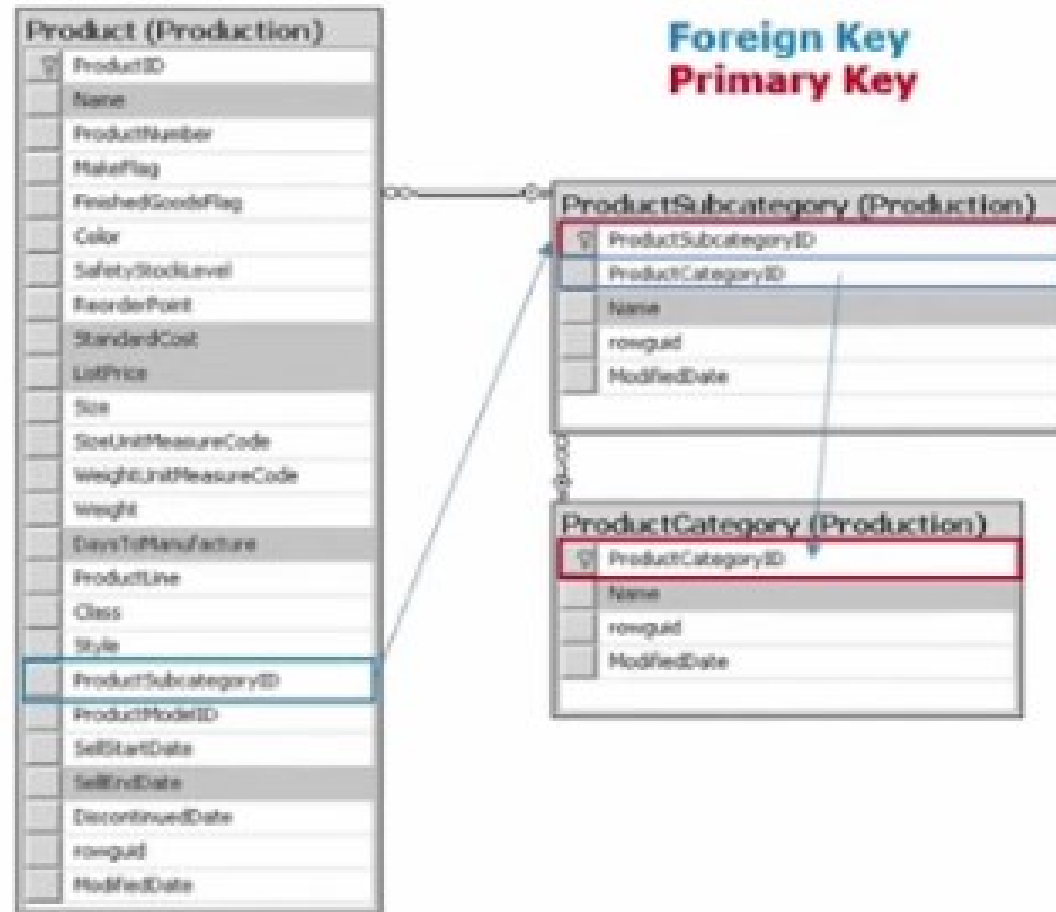

FOREIGN KEY constraint

A **FOREIGN KEY** is a column or combination of columns that are used to establish a link between data in two tables. The columns used to create the primary key in one table are also used to create the foreign key constraint and can be used to reference data in the same table or in another table

A foreign key does not have to reference a primary key, it can be defined to reference a unique constraint in either the same table or in another table

A column that participates in the foreign key constraint can accept null values, but if it contains a null value, the verification process is skipped.

Relational structure with keys

Primary Key Constraint

- A primary key constraint refers to a **single table**
- It identifies a subset of columns as **key columns**
- Fixing values for key columns must **identify** row
- **No two rows** have same values in key columns

Defining Example Schema

PKKey

Students

| | | |
|-----|-------|-----|
| Sid | Sname | Gpa |
|-----|-------|-----|

PKKey

Enrollment

| | |
|-----|-----|
| Sid | Cid |
|-----|-----|

PKKey

PKKey

Courses

| | |
|-----|-------|
| Cid | Cname |
|-----|-------|

Foreign Key Constraint

- A foreign key constraint links **two tables**
- Identifies set of **foreign key columns** in table 1
- Maps foreign key columns to **primary key** of table 2
- Values in foreign key column **must appear** as primary key
- Maps **each row** in table 1 to a row from table 2

Defining Example Schema

Summary

Primary key constraint— an attribute or set of attributes used to uniquely identify each row

Foreign key constraint – a column or combination of columns used to establish a link between data in two tables

Unique constraint - allows you to enforce uniqueness in columns other than the primary key

Unique Index - ensures the index key contains no duplicate values and that every row in the table or view is unique in some way

Types of Relationship

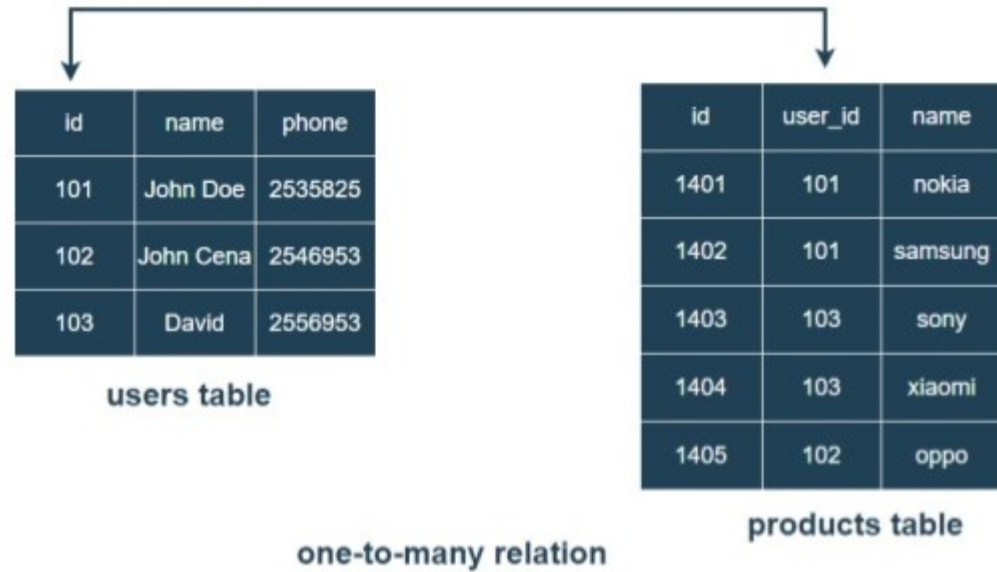

1. One-to-One relationship

□Exists between tables when only one record of the first table is related to only one record to a second table, and only one record of the second table is related to only one record to the first table

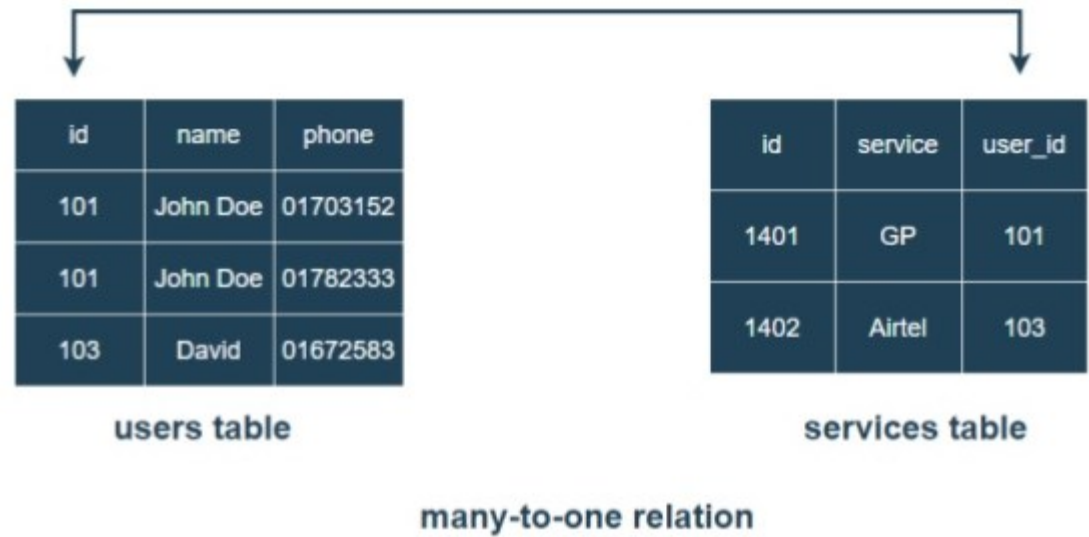

2. One-to-Many relationships

- Exists between tables when one record of the first table can be related to one or more records to a second table, but only one record from the second table can be related to a single record in the first table
- Most common relationship used to avoid or eliminate duplicate and redundant data

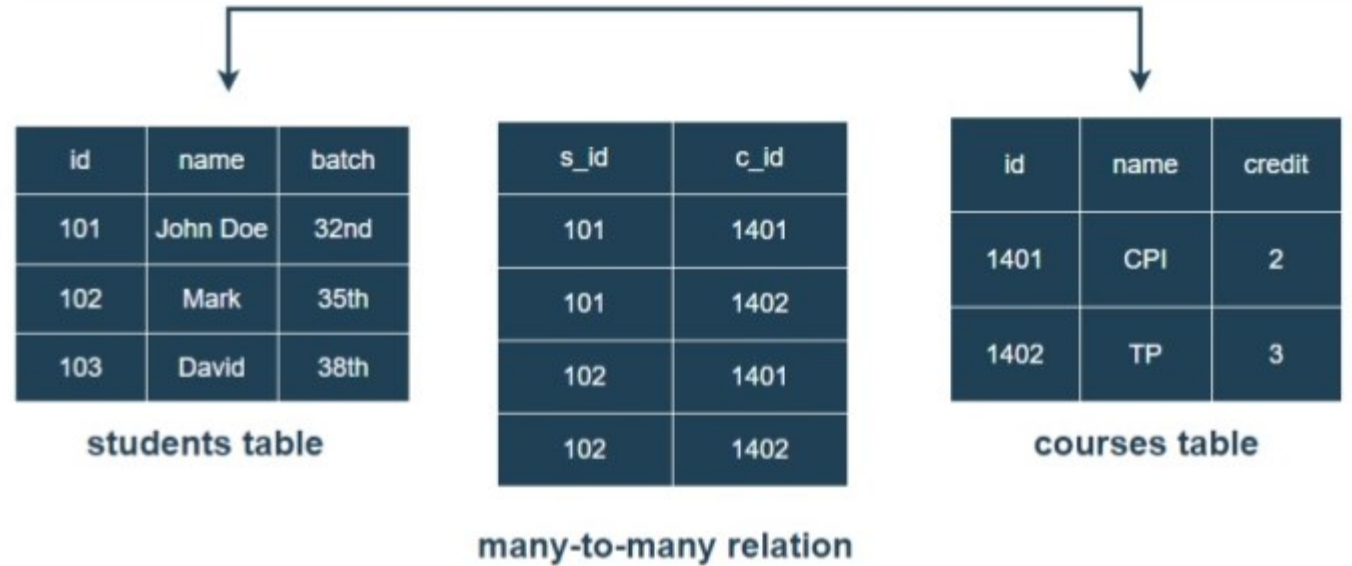

2.Many-to-one relationships

□Exists between tables when more than one record of the first table can be related to one record to a second table, but only one record from the second table can be related to a single record in the first table

3. Many-to-Many relationship

□ Exists between tables when one record of the first table can be related to one or more records to a second table, and one or more records of the second table is related to one or more records to the first table

Data normalization

Database Queries

by Angel Marchev, Jr.

Database objects

- **Table** – collection of rows and columns which are used to store information about single topic (entity). Each row is a record, with data about several attributes.
- **View** – virtual table consisting of records and columns from different tables. It is stored in the database as a query object, not as a table.
- **Procedure** – compiled list of instructions and queries, saved in the database to be run several times.

Database Interfaces

- **Form** – user interface to the database for inputting and outputting data.
- **Report** – formatted document containing outputs from a database.

Query – scripted request for extracting certain data from the database – with or without certain data processing.

Queries help you find and work with your data

In a well-designed database, the data that you want to present through a form or report is usually located in multiple tables. A query can pull the information from various tables and assemble it for display in the form or report. A query can either be a request for data results from your database or for action on the data, or for both. A query can give you an answer to a simple question, perform calculations, combine data from different tables, add, change, or delete data from a database. Since queries are so versatile, there are many types of queries and you would create a type of query based on the task.

| Major query types | Use |
|-------------------|---|
| Select | To retrieve data from a table or make calculations. |
| Action | Add, change, or delete data. Each task has a specific type of action query. |

We can use Relational Algebra to fetch data from this Table(relation)

| ID | Name | Age |
|----|------|-----|
| 1 | Akon | 17 |
| 2 | Bkon | 19 |
| 3 | Ckon | 15 |
| 4 | Dkon | 13 |

Select Name students with age less than 17

Output

| Name |
|------|
| Ckon |
| Dkon |

The output for query is also in form of a table(relation), with results in different columns

1. Use GROUP BY to combine rows
2. Use FILTER to pick rows per column

| Year | Month | Revenue |
|------|-------|---------|
| 2016 | 1 | 1 |
| 2016 | 2 | 23 |
| 2016 | 3 | 345 |
| 2016 | ... | ... |
| 2016 | 12 | 1234 |

| Year | Jan | Feb | Mar | ... | Dec |
|------|-----|-----|-----|-----|------|
| 2016 | 1 | 23 | 345 | ... | 1234 |

MS Access Query

This screenshot shows the MS Access Design View for a query named 'Query1'. The 'All Access Objects' pane on the left lists 'tblEmployee' and 'TempEmployee' under Tables, and 'Query1' under Queries. The Design grid shows the following configuration:

| Field | Table | Sort | Append To | Criteria | or |
|------------|-------------|------|------------|----------|----|
| EmployeeID | tblEmployee | | EmployeeID | | |
| FirstName | tblEmployee | | FirstName | | |
| LastName | tblEmployee | | LastName | | |
| Address1 | tblEmployee | | | | |
| JobTitle | tblEmployee | | JobTitle | | |

This screenshot shows the MS Access Datasheet View for a query named 'TempEmployee'. The ribbon includes 'Table Tools' and 'Fields'. The data is displayed in a table with the following columns: EmployeeID, FirstName, LastName, Address, and JobTitle. The data is sorted by JobTitle in ascending order.

| EmployeeID | FirstName | LastName | Address | JobTitle |
|------------|-----------|----------|---------------------|--------------------------|
| 2 | Max | Clay | 2556 Mohave St | Accounting Assistant |
| 3 | Janell | Frank | 6433 Morgan Ln | Accounting Manager |
| 4 | Claudine | Goff | 21 Berkley Ln | Administrative Assistant |
| 5 | Annemarie | Marks | 91 Forest Ln | Accounting Assistant |

QUERY DESIGN

- All queries need to be designed and should always include the following:
 - Fields
 - Tables
 - Criteria for query
 - Sort order
 - Grouping

QUERY DESIGN TEMPLATE

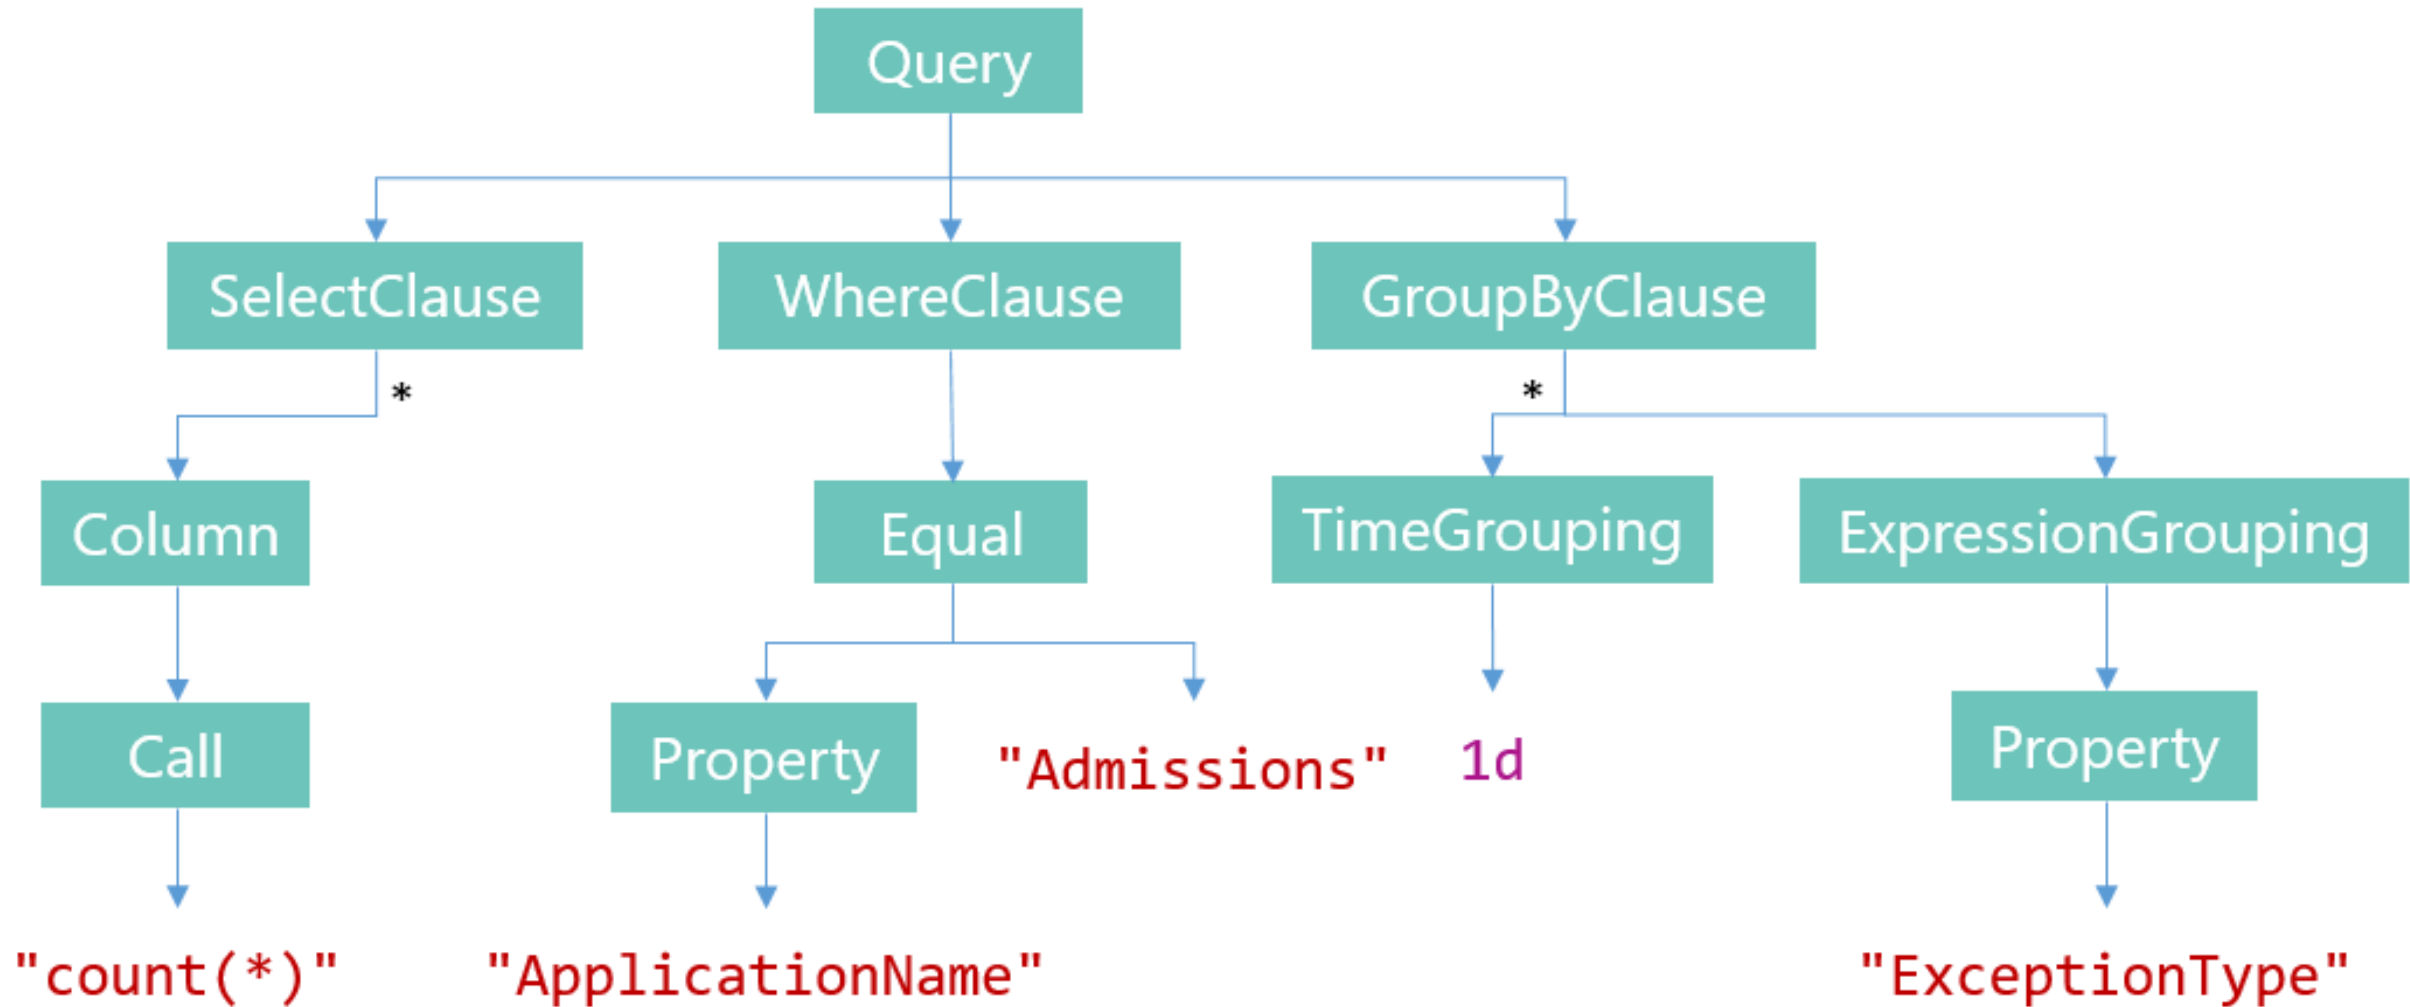

- The format for the query design table:

| | |
|------------------------|--|
| Field (s) | This shows the fields required for the query. |
| Table (s) | This shows the table each field comes from, this can be more than one. |
| Search Criteria | This shows the conditions required for the query. |
| Sort Order | If the query need to sort the answers. |

EXAMPLE

- Design a query to list Computing teachers and phone numbers with a tutor class. This should be sorted in alphabetical order.

| | |
|-----------------|---|
| Field (s) | teacherName, teacherNumber, tutorGroup, Subject |
| Table (s) | Teacher |
| Search Criteria | Subject = Computing AND tutorGroup = True |
| Sort Order | Asec |

QUERY DESIGN

- Query designs should include the information shown below
- Depending on the query, not all elements need to be filled

| | |
|------------------------------------|--|
| Field(s) and calculation(s) | |
| Table(s) and query | |
| Search criteria | |

| houseNum |
| postcode |

| Booking |
|-------------------|
| <u>bookingRef</u> |
| customerID * |
| registration * |
| daysBooked |
| startDate |

| Car |
|---------------------|
| <u>registration</u> |
| make |
| model |
| colour |
| depotID * |
| automatic |
| dailyPrice |
| mileage |

| Depot |
|-------------------|
| <u>depotID</u> |
| depotName |
| depotCity |
| onlineBookin g |
| depotHours |
| employees |

Database queries exercise

- <https://forms.gle/B4qNS3XdQqJPacqG9>

EXAMPLE 1

- Design a query to show the make, model and mileage of a car in a depot which is open all day, and where the make of car starts with 'M'.

| | |
|------------------------------------|--|
| Field(s) and calculation(s) | |
| Table(s) and query | |
| Search criteria | |
| Grouping | |
| Sort order | |

EXAMPLE 1

- Design a query to show the make, model, mileage and depot of any car in a depot that is open all day and where the make of car starts with 'M'.

| | |
|------------------------------------|---|
| Field(s) and calculation(s) | make, model, mileage, depotName, depotHours |
| Table(s) and query | car, depot |
| Search criteria | depotHours = 'All Day' and model like 'M%' |
| Grouping | |
| Sort order | |

EXAMPLE 2

- Design a query to show a customer's full name, booking ID, car make and model, and depot name for all customers who have 'e' as the 5th letter of their surname
- List the details in alphabetical order of the customer surname

| | |
|------------------------------------|--|
| Field(s) and calculation(s) | |
| Table(s) and query | |
| Search criteria | |
| Grouping | |
| Sort order | |

EXAMPLE 2

- Design a query to show a customer's full name, booking ID, car make and model, and depot name for all customers who have 'e' as the 5th letter of their surname
- List the details in alphabetical order of the customer surname

| | |
|------------------------------------|---|
| Field(s) and calculation(s) | forename, surname, bookingRef, make, model, depotName |
| Table(s) and query | customer, booking, car, depot |
| Search criteria | surname LIKE = ' _ _ _ _ e %' |
| Grouping | |
| Sort order | surname ASC |
